ABSTRACT

This study introduces a real-time unsupervised monitoring framework for monitoring sinkhole formation events during earth pressure balance (EPB) shield tunneling operations. A feature extractor (FE) is constructed by coupling variational Autoencoders structure with convolutional neural network layers (VAE-CNN) to manage the complexity of EPB operational data, including non-linearity and temporal dependencies. The monitoring framework consists of two main phases: offline modeling and online monitoring. In the offline modeling phase, an FE model is trained using data-intensive techniques to define a subspace characterizing the behavior of multivariate data without sinkhole formations. The squared prediction error (SPE) statistics and the control limits are computed for detection. During the online monitoring phase, unseen EPB data is propagated to generate SPE values and determine sinkhole events based on whether these values surpass the control limit. Sensor validity index violation counts were used to isolate the most influential variables, while the results demonstrated the superiority of the proposed VAE-CNN method, achieving a 100% detection rate and a 0.9% false alarm rate. The influential variables identified include cutter revolutions per minute, jack speed, screw pressure, torque, and cutter seal components. The monitoring system shows great potential for early warnings during EPB operations to mitigate sinkhole formation risks.

1. Introduction

The intensified urbanization and population growth witnessed in the past century have given rise to diverse urban needs, especially in urban infrastructure and effective transportation development. As cities expand, essential elements such as bridges, interchanges, roads, roundabouts, highways, and tunnels have become significant (Qiao and Huang, 2022). Tunneling, a significant process in transportation, strategic projects, and resource exploitation, has played a crucial role in advancements like subway transportation, hydroelectric plant construction, and underground mining (Pourhoseini et al., 2022).

With the rapid development of these infrastructures, tunnel boring

machines (TBM) have been broadly utilized and preferred for tunnel construction due to their advantageous operations, as they execute closed-mode maneuvers that enhance safety measures by ensuring the stability of the surrounding rock mass (Huang et al., 2022). This involves utilizing instant support with concrete linings and mitigating the risks associated with groundwater pressure under the water table (Lee et al., 2021). Furthermore, shield tunneling operations are known for their efficiency, cost-effectiveness, and environmental friendliness (Ajawah et al., 2022).

Earth pressure balance (EPB) machines are shield TBM designed to function in soft ground conditions, water pressure, high water table, karstic, and sedimentary environments (Wan et al., 2024). During EPB

TUNNELLING AND UNDERGROUND SPACE TECHNOLOGY incorporating TRENCHLESS TECHNOLOGY RESEARCH

Tunnelling and Underground Space Technology is a combination of two previous Pergamon Journals: *Underground Space*, the official journal of the American Underground-Space Association, published by Pergamon Press in cooperation with the University of Minnesota from 1975 to 1985 (Volumes 1–10); and *Advances in Tunnelling Technology and Subsurface Use*, the official journal of the International Tunnelling Association, published by Pergamon Press from 1981 to 1985 (Volumes 1–4). Research and other technical papers are refereed by a panel of experts in the field of tunnelling and underground space technology.

Trenchless Technology Research was first published as a supplement to TUST in 1986 as the official journal of the *International Society for Trenchless Technology*. Research and other related technical papers are refereed by a panel of experts in the field of trenchless technology. TTR was incorporated into TUST in 2002.
